
Sarscape For Envi 5

the envisat etm+ has been operating in 1.5.9 remote service (rtos) and uses a proprietary microprocessor that is not based on the general-purpose processor architecture used by the other envisat instruments. the rtos software provides an improved trade-off between system-level complexity and operation reliability and system availability, compared to a general-purpose processor. the etm+ was designed to comply with internationally recognised standards with respect to thermal and mechanical design, and with respect to the processing requirements in the united states. the instrument platform (also called the "airframe" or "container" by the operators) is designed to enable the instrument to support data transfer to and from the ground or to other envisat instruments in the same satellite, depending on the goal of the mission. to open and view slc files, geotiff files have been created. these files store particular collection information and support processing in envi. they were created by using the vll4s.adf collected in the slc files. this is the time resolution in days. by using the effective date as a starting point, the difference between the two dates can be used to determine the number of days between the two dates. after this number of days, the effective date can be used to determine the number of days back to the start of the acquisition. this number of days can be added to the acquisition date to find the acquisition date in days. the approximate size of the sidc is about 67,600 bytes, the exact size depends on the number of cadastral parcels in the area, which can be up to 1,800. a sidc is information developed to support the processing of the source data. the index file is a pbf or compressed run-length encoded binary file that contains vector data. each vector entry (aka "run") contains a sequence of data values that are the attributes for each source polygon. the sidc provides the following attributes for each parcel and for each feature in the parcel:

envisar sar data is organized into quadrant tiles, which are defined in the metadata of the files. this allows the radon transform to be implemented on all the available data. additionally, the metadata can be used to divide the data into the different quadrants and to define orientation. this improved radon transform algorithm provides the ability to extract surface slopes and elevations, which can be used to identify and map the range of fault surfaces and other topographic features. a new option in the sarscape interferometry processing tab, which is called radon stacking, allows for the processing of data for a series of images. the radon stacking option is useful for processing data where the reflection from the terrain varies over time. an example would be a radar that looks down over a valley where the reflection from the ground is different from the reflection from the top of the valley. the radon stacking function will produce a stacked image where each layer is the result of processing the data for the corresponding time. the envisar sar data is organized into quadrant tiles, which are defined in the metadata of the files. this allows the radon transform to be implemented on all the available data. additionally, the metadata can be used to divide the data into the different quadrants and to define orientation. this improved radon transform algorithm provides the ability to extract surface slopes and elevations, which can be used to identify and map the range of fault surfaces and other topographic features. de grandi spatio-temporal (dst) filter is a cloud-based user-friendly software program that provides high-quality filter output with a large number of robust options. dst filter is implemented in envi 5.0, and the following functions are supported: dst standard & manual, dst random and dst temporal co-registration. 5ec8ef588b
