i use background logic most often, and ive written about it before with an intro to fanuc background logic and how to use bg logic to to simplify your tp programs. if you dont need motion, you can probably do it with background logic. once the program is set up, you may run it through program mode or control mode. in program mode the program is run entirely with fanuc ncguide. the program is run in a loop until the user sends a specific command to stop it. if you

have an external device connected to the plc, you can use the "alarm" command in order to stop the program. the most appropriate part of the program is the sequence of the ladder to be used in the specific application. the ladder sequence is an instruction that guides the plc to perform its function. the ladder consists of several elements. an element is a complete instruction. it typically consists of an action, a device code, and a parameter (for example, "open door" and "10000"). after the program has been designed, the program may be tested by

running the program in "control mode". in control mode, the user operates the plc via the keyboard and mouse. the user may activate or deactivate the program, change the sequence of the ladder, and edit the ladder. the programmable controller (plc) is a device that can be programmed using ladder software. the ladder is a sequence of instructions used by plcs to perform a specific task. the ladder instructions are translated to binary code that is executed by the plc. if the translated ladder is incomplete, the plc will fail to

execute. 5ec8ef588b
