Microsoft Hyper-v Network Switch Default Miniport Driver Windows 8.1 131

[Download](#)

windows server (hyper-v) hyper-v network virtual switch describes the virtual switch in the same way. the windows hyper-v hyper-v network virtual switch role provides a mechanism to connect a virtual machine to physical network devices (such as a storage area network device, a port on a switch, or a host computer). it says (under the role behavior settings): the windows hyper-v hyper-v network virtual switch role enables you to configure network settings in a windows server (hyper-v) virtual machine. this is commonly used

to connect virtual machines to physical network adapters (such as a storage area network device, a port on a switch, or a host computer). this role is designed to connect a virtual machine to one physical adapter. you cannot use this role to connect two virtual machines to the same physical adapter. i have experienced an issue where virtual machines running on hyper-v on a cisco ucs-m server can no longer connect to the switch. the hyper-v switches fail over to the physical switch. the physical switch is cisco catalyst 2960-x and the switch console can no longer be accessed. the virtual machines still work fine on other switches. i suspect it may be a network adapter driver issue. in any case, the following describes my situation. when a clustered virtual machine is live migrated, there is the potential for a minor service outage. the mac address(es) of the virtual machines virtual adapter(s) must be unregistered from the source

virtual switch (and therefore its attached physical switch) and re-registered at the destination. if you are using dynamic mac addresses, then the macs may be returned to the source hosts pool and replaced with new macs on the destination host, in which case a similar de-registration and registration sequence will occur. all of this happens easily within the standard tcp timeout window, so in-flight tcp communications should succeed with a brief and potentially detectable hiccup. udp and all other traffic with non-error-correcting behavior (including icmp and igmp operations like ping) will be lost during this process. hyper-v performs the de-registration and registration extremely quickly the duration of the delay will depend upon the amount of time necessary to propagate the mac changes throughout the network.
